ENHANCED CIRCULATION EFFECTOR
COMPOSITION AND METHOD

5

Field of the Invention

The present invention relates to an enhanced-circulation effector composition and method for treating a subject with small effector molecules which are normally subject to rapid renal clearance from the bloodstream.

Background of the Invention

A number of emerging or current therapies involve intravenous injection of small (less than 50 Kdaltons) protein, polypeptide or polysaccharide effectors. Such effectors can include F₂ antibody fragments, for use in active immunity; cytokines and cellular growth factors, for stimulating immunological inflammatory responses; hormones; and polysaccharides, which are capable of interacting with endothelial cell receptors to competitively block neutrophil binding to activated endothelial cells lining the blood vessel (Katre, Philips, Waldmann).

Other small polypeptide effectors have been proposed for use in blocking viral infection of target cells in the blood, such as a CD4+ glycopeptide which is effective to inhibit binding of human immunodeficiency virus (HIV) to CD4+ cells (Capon, Janeway).

Polymyxin B, a small basic peptide which is rapidly excreted by the kidneys, is known to react with and neutralize gram-negative bacterial endotoxins, specifically E. coli 0111:B4 liposaccharide (LPS) (Baldwin). It is not often administered parenterally as a treatment for septic shock syndrome, because high doses of polymyxin B are required for effective treatment. High doses can be fatal, due to renal toxicity, making advanced stages of septic shock difficult to treat.

The problem of rapid renal clearance observed with polymyxin B is also applicable to other small peptides, such as those discussed above, which have been used for parenteral treatment of disease. In general, circulating proteins which are smaller than about 50-60 Kdaltons will be

cleared by the kidneys with a lifetime less than 1-2 hours.

In some cases, peptide molecular weight can be increased above the threshold 50-60 Kdalton size by derivatizing the peptide with biologically compatible polymers, such as polyethyleneglycol (PEG) (e.g., U.S. Patent No. 4,179,337). However, this strategy may not always be effective for small effectors, e.g., those with molecular weights less than about 5-10 Kdalton. Moreover, derivatizing a polypeptide with a plurality of PEG chains may destroy or reduce the polypeptide activity, and/or mask key activity sites of the polypeptide.

Summary of the Invention

The invention includes, in one aspect, a method of treating a subject by parenteral administration of a polypeptide or polysaccharide effector which is rapidly removed from the bloodstream by renal clearance in free form. The method includes parenterally administering to the subject, a liposome composition containing liposomes having an outer layer of polymer chains and the effector covalently attached to the distal ends of said chains. A preferred polymer is polyethylene glycol with chain lengths between about 1,000 and 10,000 daltons molecular weight.

Preferred effectors include:

- (a) an antibody F_{ab} fragment specific against a blood-circulating pathogen, for use in treating the subject for infection by the pathogen;
- (b) a CD4 glycoprotein, for use in treating the subject for infection by human immunodeficiency virus (HIV);

(c) a cytokine or cellular growth factor, for use in stimulating an immune response in the subject;

(d) a mono or polysaccharide, such as sialyl Lewis^x, which binds to endothelial leukocyte adhesion molecule (ELAM), for use in treating a vascular inflammation related to neutrophil recruitment into sites of inflammation;

(e) IL-1 inhibitor or IL-1RA, for treating the subject to achieve immune-response suppression;

(f) polymyxin B, or polymyxin B decapeptide, for treating the subject for septic shock;

(g) a peptide hormone, for treating diseases subject to peptide hormone control; and

(h) a peptide, for use in blocking a ligand-receptor cell binding event.

In one specific embodiment, the invention includes a method of preventing progression of gram-negative bacteremia to septic shock and a method of treating acute septic shock by administering to a subject, a liposome composition containing liposomes having an outer layer of polyethylene glycol (PEG) chains and polymyxin B attached to the distal ends of the polymer chains.

In another aspect, the invention includes a composition of liposomes, each having an outer layer of polymer chains, typically polyethylene glycol chains, and one of the above effectors (a)-(h) attached to the distal ends of the chains.

These and other objects and features of the invention will become more fully apparent when the following detailed description of the invention is read in conjunction with the accompanying drawings.

Brief Description of the Drawings

Fig. 6 shows steps in the synthesis of a derivatized DSPE lipid having a PEG terminal hydrazide group;

20 Figs. 7A-7D show steps in the synthesis of a derivatized DSPE lipid having a PEG terminal activated group (7A) which can be used to couple a variety of amine-containing groups (7B-7D) to the PEG polymer ends;

25 Fig. 8 shows steps in forming another PE derivatized by a PEG spacer chain having a hydrazide group;

30 Fig. 9 shows the covalent coupling of a peptide, via a sulfhydryl group, to the maleimide of a DSPE carbamate of PEG bis (amine) shown in Fig. 1;

35 Fig. 10 shows the covalent coupling of a peptide, via a sulfhydryl group, to a disulfide linkage-containing propionamide of a DSPE carbamate of PEG bis (amine) maleimide of the DSPE carbamate of PEG bis (amine) shown in Fig. 2;

Fig. 11 shows the covalent coupling of a peptide, by reductive amination, to the aldehyde of an ethylene-linked derivative of DSPE carbamid of PEG (PEG), shown in Fig. 3; Fig. 12 shows a plot of a time course of gallium-67 labelled liposomes composed of hydrazide PEG-DSPE, partially hydrogenated egg phosphatidylcholine (PHEPC), and cholesterol (PEG-HZ fluid liposomes) or hydrazide PEG-DSPE, hydrogenated serum phosphatidylcholine (HSPC), and cholesterol (PEG-HZ rigid liposomes) in the bloodstream; and Fig. 13 shows the amino acid sequences for peptides identified by SEQ ID NOS:1-10, in conventional single-letter amino acid code.

15

Detailed Description of the Invention

I. Definitions

Unless otherwise indicated, the terms below have the following meaning:

20 "Vesicle-forming lipid" refers to any lipid capable of forming part of a stable micelle or liposome composition and typically including one or two hydrophobic acyl hydrocarbon chains or a steroid group and may contain a chemically reactive group, such as an amine, acid, ester, aldehyde or alcohol, at its polar head group.

25 "Effector" refers to polypeptides, mono or polysaccharides, and glycopeptides. Polypeptides, polysaccharides or glycopeptides may have sizes up to about 50-60 Kdaltons.

30

II. Effector Composition

The invention includes, in one aspect, a liposome composition for use in treating a subject with a small polypeptide or polysaccharide effector molecule which is itself, in free form, removed rapidly from the bloodstream by renal

35

clearance. The composition includes a liposomal carrier composed of liposomes having an outer layer formed of hydrophilic polymer chains, e.g., PEG. The effector is attached to the distal ends of the polymer in a portion of the derivatized vesicle-forming lipid. The effector is attached to distal end of a polymer chain to preserve the biological activity of the effector, such as behaving as a member of a ligand-receptor binding pair. The preparation of the composition follows the general procedures below.

A. Lipid Components

The liposomal carrier of the composition is composed of three general types of vesicle-forming lipid components. The first includes vesicle-forming lipids which will form the bulk of the vesicle structure in the liposome.

Generally, these vesicle-forming lipids include any amphipathic lipids having hydrophobic and polar head group moieties, and which (a) can form spontaneously into bilayer vesicles in water, as exemplified by phospholipids, or (b) are stably incorporated into lipid bilayers, with its hydrophobic moiety in contact with the interior, hydrophobic region of the bilayer membrane, and its polar head group moiety oriented toward the exterior, polar surface of the membrane.

The vesicle-forming lipids of this type are preferably ones having two hydrocarbon chains, typically acyl chains, and a polar head group. Included in this class are the phospholipids, such as phosphatidylcholine (PC), PE, phosphatidic acid (PA), phosphatidylinositol (PI), and sphingomyelin (SM), where the two hydrocarbon chains are typically between about 14-22 carbon atoms in length, and have varying degrees of unsaturation.

The above-described lipids and phospholipids whose acyl chains have a variety of degrees of saturation can be obtained commercially, or prepared according to published methods. Other lipids that can be included in the invention are glycolipids and sterols, such as cholesterol.

The second general component includes a vesicle-forming lipid which is derivatized with a polymer chain which will form the polymer layer in the composition. The vesicle-forming lipids which can be used as the second general vesicle-forming lipid component are any of those described for the first general vesicle-forming lipid component. Vesicle forming lipids with diacyl chains, such as phospholipids, are preferred. One exemplary phospholipid is phosphatidylethanolamine (PE), which provides a reactive amino group which is convenient for coupling to the activated polymers. An exemplary PE is distearyl PE (DSPE).

The preferred polymer in the derivatized lipid, is polyethyleneglycol (PEG), preferably a PEG chain having a molecular weight between 1,000-10,000 daltons, more preferably between 2,000 and 5,000 daltons. Other hydrophilic polymers which may be suitable include polyvinylpyrrolidone, polymethyloxazoline, polyethyloxazoline, polyhydroxypropyl methacrylamide, polymethacrylamide and polydimethylacrylamide, polylactic acid, polyglycolic acid, and derivatized celluloses, such as hydroxymethylcellulose or hydroxyethylcellulose.

Additionally, block copolymers or random copolymers of these polymers, particularly including PEG segments, may be suitable. Methods for preparing lipids derivatized with hydrophilic polymers, such as PEG, are well known e.g., as described in co-owned U.S. Patent No. 5,013,556.

The third general vesicle-forming lipid component is a lipid anchor by which the effector is anchored to the liposomes, through a polymer chain in the anchor. Additionally, the effector is positioned at the distal end of the polymer chain in such a way so that the biological activity of the effector is not lost. The lipid anchor has a hydrophobic moiety which serves to anchor the lipid in the outer layer of the liposome bilayer surface, a polar head group to which the interior end of the polymer is covalently attached, and a free (exterior) polymer end which is or can be activated for covalent coupling to the effector. Methods for preparing lipid anchor molecules of this types are described below.

B. Liposome Preparation

The liposomes may be prepared by a variety of techniques, such as those detailed in Szoka et al, 1980. Multilamellar vesicles (MLVs) can be formed by simple lipid-film hydration techniques. In this procedure, a mixture of liposome-forming lipids of the type detailed above dissolved in a suitable organic solvent is evaporated in a vessel to form a thin film, which is then covered by an aqueous medium. The lipid film hydrates to form MLVs, typically with sizes between about 0.1 to 10 microns.

The lipids components used in forming the liposomes are preferably present in a molar ratio of about 70-90 percent vesicle forming lipids, 1-25 percent polymer derivatized lipid, and 0.1-5 percent lipid anchor. One exemplary formulation includes 50-70 mole percent underivatized PE, 20-40 mole percent cholesterol, 0.1-1 mole percent of a PE-PEG (3500) polymer with a chemically reactive

group at its free end for effector coupling, 5-10 mole percent PE derivatized with PEG 3500 polymer chains, and 1 mole percent α -tocopherol. The liposomes are preferably prepared to have substantially homogeneous sizes in a selected size range, typically between about 0.03 to 0.5 microns. One effective sizing method for REVs and MLVs involves extruding an aqueous suspension of the liposomes through a series of polycarbonate membranes having a selected uniform pore size in the range of 0.03 to 0.2 micron, typically 0.05, 0.08, 0.1, or 0.2 microns. The pore size of the membrane corresponds roughly to the largest sizes of liposomes produced by extrusion through that membrane, particularly where the preparation is extruded two or more times through the same membrane. Homogenization methods are also useful for down-sizing liposomes to sizes of 100nm or less (Martin).

C. Effector Component

The effector in the composition is a therapeutic polypeptide, mono or polysaccharide, or glycopeptide characterized, when administered intravenously in free form, by rapid clearance from the bloodstream, typically within 1-2 hours. Below are described preferred effectors for use in the invention.

1. F_a Fragment. The F_a fragment is one which has neutralizing activity against a given pathogen. The composition is used as a passive vaccine effective to provide humoral immunity against one of a variety of selected pathogenic antigens.

F_a fragments of neutralizing antibodies can be prepared according to conventional methods (Harlow). The fragment is preferably from a

humanized monoclonal antibody (M_{ab}). Such antibodies can be prepared by published recombinant DNA methods (Larrick). The antibody is preferably coupled to liposomal hydrophilic polymer groups via sulfhydryl linkages, as described above.

2. CD4 Glycoprotein Effector. The CD4 glycopeptide is a region of the CD4 receptor of CD4+ T cells (Capon). The effector acts to block HIV infection of CD4+ T cells by blocking gp120-mediated HIV binding to the CD4 receptor. The effector can be produced according to known recombinant methods (Maniatis).

3. Cytokines. The cytokines given in Table 1 below are examples of cytokines which are useful in the present invention. The cytokines may be obtained by recombinant production methods, according to published procedures. The therapeutic uses of the individual cytokines have been described in the literature (see, for example, Abbas). Some cytokine effectors may be administered on a short term basis to enhance a weak immunogenic or weak microbicidal response. The effectors may be administered on a long term basis as part of a therapy treatment for cancer or AIDS (Waldmann).

Table 1

CYTOKINE	POLYPEPTIDE SIZE
A. Mediators of Natural Immunity	
IFN-alpha	18 kD (monomer)
IFN-beta	20 kD (monomer)
Tumor necrosis factor (TNF)	17 kD (homotrimer)
Interleukin-1 (alpha and beta)	17 kD (monomer)
Interleukin-6	26 kD (monomer)

CYTOKINE	POLYPEPTIDE SIZE
Interleukin-8's	8-10 (monomer or dimer)
B. Mediators of Lymphocyte Activation, Growth and Differentiation	
Interleukin-2	14-17 kD (monomer)
Interleukin-4	20 kD (monomer)
Transforming growth factor (beta)	14 kD (monomer or dimer)
C. Mediators of Effector Cell Adhesion	
Gamma Interferon	21-24 kD (homodimer)
Lymphotoxin	24 kD (homotrimer)
Interleukin-5	20 kD (monomer)
D. Mediators of Immature Leukocyte Growth and Differentiation	
Interleukin-3	20-26 kD (monomer)
Granulocyte-macrophage Colony Stimulating Factor	22 kD (monomer)
Macrophage Colony Stimulating Factor	40 kD (dimer)
Granulocyte CSF	19 kD (monomer)
Interleukin-7	25 kD (monomer)

20 4. ELAM-1 Binding Inhibitor. Inflammation causes the expression of a polypeptide, endothelial leukocyte adhesion molecule-1 (ELAM-1), on the surface of endothelial cells of blood vessels, adjacent to sites of inflammation. ELAM-1, in turn, recognizes and
25 binds a polysaccharide moiety, sialyl Lewis^x on surfaces of neutrophils, and recruits neutrophils to sites of inflammation. By preventing the recognition and binding of neutrophils by ELAM-1, excessive inflammatory responses due to conditions, such as
30 reperfusion injury, septic shock, and chronic inflammatory diseases, can be avoided.

In this embodiment, the effector is the tetrasaccharide, sialyl Lewis^x, recognized by ELAM-1 (Phillips), for therapeutical use in preventing
35 excessive recruitment of neutrophils to sites of

inflammation in the blood stream. The effector is produced by the glycosylation mutants of Chinese hamster ovary (CHO) cells, and may be obtained in purified form from the cultured cells (Phillips).

5 Alternatively, the effector is produced by chemical and/or enzymatic synthesis (Borman, Ichikawa).

5. Inhibitors of IL-1 Activity. The effector in this embodiment is an IL-1 inhibitor, or IL-1 receptor antagonist (IL1RA), which blocks binding
10 of IL-1 to receptors on lymphocyte cell surfaces (Stylianou).

IL-1 production is stimulated by both endotoxins which cause septic shock and exotoxins which cause toxic shock syndrome (Dinarello). IL-1 production
15 during septic shock or toxic shock may exacerbate the clinical symptoms observed in patients. Therefore, use of an IL-1 inhibitor effector to decrease the clinical symptoms associated with either toxic shock or septic shock may be beneficial.

20 IL-1 inhibitor is a 52 to 66 Kd polypeptide that binds specifically to IL-1 to inhibit its immunostimulatory responses. IL1RA is a 23 to 25 Kd polypeptide that competes with binding of IL-1 to its cell surface receptors to inhibit IL-1's
25 immunostimulatory responses.

6. Polymyxin B. This effector is a cationic detergent with a hydrophobic portion (6-methyloctanoyl) and a short basic decapeptide portion. Polymyxin B reacts with and neutralizes gram-negative
30 bacterial endotoxins, specifically *E. coli* 0111:B4 liposaccharide (LPS) (Baldwin). Polymyxin B is used in the treatment of gram-negative bacterial infections. Since polymyxin B must be administered frequently and in high doses because of its rapid clearance from the
35 bloodstream, it causes severe irreversible kidney damage. Polymyxin B can be chemically synthesized or

isolated from spore-forming gram-positive bacilli, such as *Bacillus polymyxa*.

Alternatively, the effector is an 11.8 Kdalton peptide isolated from amebocytes of *Limulus polyphemus*,
5. *limulus antilipopolysaccharide factor* (LALF). LALF neutralizes meningococcal lipooligosaccharide, as well as other gram-negative endotoxins, and can be used to treat gram-negative sepsis (Wainwright).

7. Peptide Hormone. This effector can be
10 used in the treatment of various diseases. In one embodiment, the effector is parathyroid hormone (PTH) which is 84 amino acids in length and can inhibit osteoblast division. Certain bone cancers are characterized by uncontrolled osteoblast division
15 (Kano). Alternatively, the peptide hormone can be used to target a liposome to cells that contain receptors for a specific peptide hormone.

8. Peptide. A number of pathological conditions involve ligand-specific cell-binding events,
20 where a molecule adheres to the surface of a cell via a ligand. For example, the ligand laminin mediates the binding of malignant cells to basement membranes, an initial step in formation of metastatic tumors. Attachment of some bacteria, such as *Pseudomonas*, to
25 host epithelial cells is mediated by a ligand-binding event, as is the binding of viral particles to host cells. The infection of cells by human immunodeficiency virus (HIV) also requires ligand-specific cell-binding events as a part of the infection
30 process. The cell-binding events in these processes are specific and, therefore, in many cases it is possible to inhibit the cell-binding event by exposing the cell to a small peptide which competes with the ligand for receptor sites. Inhibition of the cell-binding event potentially results in arresting the
35 infection process.

In this embodiment, the effector is a peptide effective to block a ligand-receptor cell-binding event. The peptide may be ne effective t inhibit infection by human immunodeficiency virus (HIV), by
5 inhibiting virus-particle attachment to T cells, where the peptide has one of the amino acid compositions (Fig. 13): SEQ ID NO:1 (Nehete); SEQ ID NO:2 (Nehete); SEQ ID NO:3 (Nehete); SEQ ID NO:4 (Nehete); or SEQ ID NO:5 (Nehete).

10 The peptide may be effective for retarding tumor metastasis, by inhibiting the binding of free tumor cells to basement membrane cells, where the peptide has one of the amino acid sequences: SEQ ID NO:6 (Iwamoto); SEQ ID NO:7 (Iwamoto); SEQ ID NO:8 (Humphries); SEQ ID
15 NO:9 (Iwamoto); or SEQ ID NO:10 (Kawasaki).

Other binding-related peptides, such as those useful for inhibiting *Pseudomonas* infection, by inhibiting bacterial attachment to epithelial cells (e.g., Sastry, Lee) may be employed.

20 D. Attachment of Effector to Liposome Carrier

For effector attachment to liposome carriers the free polymer end of a lipid anchor is activated prior to effector coupling. In the following specific examples, both lipid anchor formation and activation
25 reactions are described. The reactions are shown with respect to the free lipid, distearylphosphatidylethanolamine (DSPE). The activated lipid anchors are then incorporated into liposomal carriers, as described above.

30 One advantage of activating the PEG terminal group of the lipid anchor prior to liposome formation is that a broader range of reaction solvents and reaction conditions may be employed. Further, the liposomes themselves are not exposed to the activating reagents.
35 Thus, the need to remove reagent contaminants from the liposomes is avoided.

It will also be appreciated that the activation reactions may be performed after lipid anchor incorporation into liposomal carriers. In some coupling reactions it may be more desirable to activate the terminal PEG groups on preformed liposomes. One advantage of this approach is that the activation reaction is confined to the outer, surface-accessible lipids, and thus the activated groups can be completely quenched prior to use of the composition in therapy. The approach is also preferred for reactions in which the activated PEG termini are unstable in water.

Fig. 1 shows the synthesis of a DSPE derivatized with a PEG chain and having an activated chemical group at the chain's free end. Initially, PEG bis (amine) (compound I) is reacted with 2-nitrobenzene sulfonyl chloride to generate the monoprotected product (compound II). Compound II is reacted with carbonyl diimidazole in triethylamine (TEA) to form the imidazole carbamate of the mono 2-nitrobenzene-sulfonamide (compound III).

Compound III is reacted with DSPE in TEA to form the derivatized PE lipid protected at one end with 2-nitrobenzyl sulfonyl chloride. The protecting group is removed by treatment with acid to give the DSPE-PEG product (compound IX) having a terminal amine on the PEG chain. Reaction with maleic acid anhydride gives the corresponding maleamic product (compound V), which on reaction with acetic anhydride gives the desired PE-PEG-maleimide product (compound VI). Details of the reactions are given in Example 1.

The compound is reactive with sulfhydryl groups, for coupling polypeptides through a thioether linkage, as illustrated in Fig. 8.

Fig. 2 illustrates the synthesis of another derivatized lipid useful for coupling sulfhydryl-containing polypeptides to the polymer terminal end of the derivatized lipid. Here the PE-PEG (compound IV)

from above is treated with N-succinimidyl-3-(2-pyridyldithio) propionamide (compound VII) to form the anchor lipid PE-PEG (compound VIII). The compound can react with a sulfhydryl group of a peptide to couple peptide to the lipid through a disulfide linkage as illustrated in Fig. 9.

Another reaction method for coupling a protected polyalkylether to a lipid amine is shown in Fig. 3. In this reaction scheme, PEG (compound IX) is initially protected at one of its terminal OH ends by a trimethylsilane group, as shown at the top in Fig. 5. The protected PEG (compound X) is reacted with the anhydride of trifluoromethyl sulfonate to activate the free PEG end with trifluoromethyl sulfonate (compound XI). Reaction of the activated compound with a lipid amine, such as PE, in the presence of triethylamine, and release of the trimethylsilyl protective group by acid treatment, gives the PE-PEG derivative (compound XII) containing a terminal alcohol group which is oxidized in the presence of dimethylsulfoxide (DMSO) and acetic anhydride to convert the terminal OH to an aldehyde group (compound XIII) which can be coupled to a peptide via reductive amination, as illustrated in Fig. 10. Reaction details are given in Example 2.

More generally, the derivatized lipid components can be prepared to include a lipid-polymer linkage, such as a peptide, ester, or disulfide linkage, which can be cleaved under selective physiological conditions, such as in the presence of peptidase or esterase enzymes or reducing agents, such as glutathione, present intracellularly.

An alternative general method for preparation of lipid derivatives of PEG suitable for coupling to effector molecules involves omega-amino carboxylic acids of PEG (such as compound XIV) as starting material and is illustrated in Figs. 4 and 5. Methods for preparing such heterobifunctional PEG derivatives

have been described by Zalipsky, et al., (1986; 1990). In the Fig. 4 reaction scheme, an omega-amino carboxylic acid of PEG (Zalipsky, et al., 1986) is reacted with maleimido propionate N-hydroxysuccinimide ester (MPS, Pierce), using an excess of MPS. The carboxyl group of the resulting maleimido-PEG (compound XV) is then reacted with a lipid amine, such as PE, in the presence of N-hydroxysuccinimide, to link the PEG to the lipid through an amide linkage (compound XVI). The maleimido group at the "free" end of the polymer is reactive towards thiol-containing ligands, proteins, e.g., immunoglobulins and fragments thereof.

A related scheme is illustrated in Fig. 5, which shows initial formation of a terminal bromoacetamide group on a PEG carboxylic acid (compound XVII), by reacting an omega-amine carboxylic acid of PEG (compound XIV) with bromoacetyl N-hydroxysuccinimide ester. The PEG is then coupled to a suitable lipid amine, such as PE, as above, to form the derivatized lipid (compound XVIII). The bromoacetamide group, being more selective and more stable than a maleimide group, will allow more flexibility in the methods used for liposome formation and loading.

The reaction scheme shown in Fig. 6 is for the preparation of a derivatized lipid in which the free PEG end is an OH group (omega OH group). In the reaction illustrated in Fig. 6, the omega-hydroxy carboxylic acid of PEG (compound XIX) (Zalipsky, 1990) is esterified with methanol, to protect the terminal acid group (compound XX). The terminal hydroxyl group is then converted into a functional group reactive towards primary amines (Zalipsky, 1992a), for example, a succinimidyl carbonate (SC) derivative (compound XXI). This compound is formed by reacting compound XX with phosgene, with subsequent reaction with N-hydroxysuccinimide (Zalipsky, 1992b). The resulting SC-PEG-CO₂-Me (XXI) reacts with a lipid amine, such as DSPE,

to form the DSPE-PEG-CO₂-Me (compound XXII). The methyl ester can be cleanly hydrazinolized to yield PE-PEG-CO-N₂H₃ (compound XXIII), as shown. This hydrazide-containing PEG-lipid is incorporated into liposomes by conventional methods. The hydrazide group can be used for attachment of aldehyde or ketone containing effector molecules.

Such carbonyl groups exist or can be easily generated on numerous carbohydrate containing molecules, e.g. oligosaccharides, nucleotides, low molecular weight glycosides, lectins, immunoglobulins and other glycoproteins by chemical (periodate oxidation) or enzymatic reactions (galactose oxidase). The linkages formed, hydrazones, are reasonably stable at pH \geq 7.5, but are cleavable by acid catalyzed hydrolysis at lower pH values. These linkages can be stabilized by reduction, e.g., with sodium cyanoborohydride. An advantage of this approach is the stability of hydrazide groups which will allow for the use of a wide array of liposome formulations and loading protocols.

Alternatively, as illustrated in Fig. 7A, the ω -hydroxy carboxylic acid of PEG (compound XIX) can be used for reaction with amino groups of PE derivatives, can be initially coupled to the amine lipid, e.g., DSPE, to form the derivatized lipid (compound XXIV). The terminal OH group of this conjugate can be activated, for example, with disuccinimidyl carbonate (DSC), to form SC-PEG-DSPE (compound XXV) for selective reactions with a variety of amino-group containing compounds. Chemical reactions are described in Example 4. These amino-group containing compounds will also possess at least one other functional group to which numerous effector molecules may be attached. The attachment of the effector molecules may occur before or after liposome formation.

In one case, as illustrated in Fig. 7B, the SC-PEG-DSPE is reacted with 2-aminoethanedithiopyridine. The derivative formed (compound XXVI) can be used in two ways. The dithiopyridin group is reactive towards thiol-containing molecules and it is quite stable in a variety of conditions. Using mild reducing agents, e.g., β -mercaptoethanol, it is possible to convert the dithiopyridine groups on the liposomes into free thiols, which in turn can be used in various conjugation procedures involving ligands containing alkylating maleimido or bromoacetate groups or reactive mixed disulfide groups like dithiopyridine.

In the reaction illustrated in Fig. 7C, the SC-PEG-DSPE is reacted with aminopropanediol, producing a diol terminated PEG-lipid (compound XXVII). After incorporation into a liposome, the diol can be oxidized with periodate under mild conditions ($[IO_4^-] \leq 10$ mM, 4°C) to provide a reactive aldehyde. The aldehyde containing PEG-liposomes will react irreversibly with a variety of amino-containing effector molecules in the presence of sodium cyanoborohydride.

In the reaction illustrated in Fig. 7D, SC-PEG-DSPE is coupled to a galactosamine. The galactose residue on the derivatized lipid (compound XXVIII) can then be enzymatically oxidized by galactose oxidase. The aldehyde bearing PEG-liposomes obtained by this process can be used for conjugation with amino-group containing effector molecules. In addition to the mildness of the reaction conditions, the aldehyde groups are solely generated on the outer surface of the liposome.

Additionally, there is evidence that oxidized galactose residues are useful for stimulation of the immune system, specifically for T cell activation. A liposome having oxidized galactose residues on its surface is likely to act as an adjuvant and might be useful in vaccines (Zheng).

In another procedure, illustrated in Figure 8 and described in Example 5, DSPE-PEG-hydrazide is prepared. First PEG is reacted with ethyl isocyanat acetate in the presence of triethylamine to generate mono and dicarboxylated species of PEG. The monocarboxylated species is purified by ion-exchange chromatography on DEAE-Sephadex (compound XXIX, identical to compound XIX). Compound XXIX is reacted with tert-butyl carbazate to generate the hydroxy Boc-hydrazide derivative of PEG (compound XXX). The free hydroxyl group is activated by reaction with disuccinimidyl carbonate to activate the terminal hydroxyl group (compound XXXI) prior to reaction with DSPE to generate product (compound XXXII). Compound XXXII is deprotected with 4M HCl in dioxane exposing the free hydrazide group. Lipid-PEG-hydrazide is the incorporated into liposomes. These hydrazide groups are reactive towards aldehydes, which as described above can be generated on numerous biologically relevant compounds.

The methods just described may be applied to a variety of lipid amines, including PE, cholesteryl amine, and glycolipids with sugar amine groups. It will be appreciated that a variety of alternative coupling reactions, in addition to those just described, are suitable for preparing vesicle-forming lipids derivatized with hydrophilic polymers such as PEG, having terminal groups which are activated or are reactive in protein coupling reactions.

1. Maleimide Coupling. Maleimides are widely used protein modifying reagents and are especially useful when the maleimide is one of two functional groups in a heterobifunctional crosslinking reagent. The reaction of maleimides with sulfhydryl groups involves Michael addition of the mercaptane group to the activated double bond. Reaction with amino groups occurs by the same mechanism, but at a much slower

rate. Since mercaptane is the most reactive species, particularly at neutral pH, the maleimide group can be used to target a small number of sulfhydryl groups and good selectivity is usually achieved.

5 In one preferred embodiment, a derivatized lipid, such as PE-PEG, is formed with a terminal maleimide group (compounds VI and XVI), as illustrated in Figs. 1 and 4 above. The lipid, after incorporation into liposomes, is then reacted with a sulfhydryl-containing
10 effector, typically a polypeptide, under suitable coupling conditions. The reaction of the maleimide lipid (compound VI or XVI) with a peptide sulfhydryl group is illustrated in Fig. 9. As shown, the reaction couples the protein to the lipid polymer through a
15 thioether linkage, to give the derivatized PE (compound XXXIII). Use of the reaction to couple proteins to liposomes is described in Example 6.

In this example the efficiency of β -galactosidase coupling to liposomes containing a maleimide coupling
20 agent in the presence or absence of PE-PEG3500 is compared. The reactions were carried out with liposomes prepared to contain, as the maleimide coupling agent, either (a) the DSPE derivative of succinimidyl 4-(p-maleimidophenyl)butyrate (MBP), (b)
25 the DSPE derivative of N-(11-maleimido-undecanoyl) (C11), or (c) the maleimide of PE-PEG3500.

After the coupling reaction, performed as described above for (a)-(c), the amount of liposome-bound enzyme was quantitated. Recovery of liposomes
30 was measured by scintillation counting and the recovery of protein was measured by the beta-galactosidase assay and direct quantitation of the protein amount.

The maleimide of the DSPE carbamide of PEG3500 was very effective in crosslinking β -galactosidase to liposomes, either in the presence or absence of PE-PEG3500
35 chains. As seen in Table 2, there was essentially no difference in the amount of protein crosslinked to

either type of liposome in two separate experiments. In addition, the amount of protein coupled to the PE-PEG mal imide was much higher than to either the MPB or MPB-C₁₁ maleimides. The presence of "non-activated" PE-PEG3500 in the liposomes had little effect on the levels of coupling of the protein to PE-PEG-maleimide liposomes, but inhibited the level of protein coupling to liposomes containing either the MPB lipid, or the MBP-C₁₁ lipid.

Table 2

"Phenotype"		ng Protein/ μmol Lipid*	
PEG-DSPE	Crosslinker	10 mM 2-ME	
-	MPB		1609/2284
-	MPB	+	(-80)
+	MPB		(-282)
-	C ₁₁		690
-	C ₁₁	+	847
+	C ₁₁		358 (-157)
+	C ₁₁	+	80
-	3500		10,033
-	3500	+	572
+	3500		10,765/12,412
+	3500	+	110

* Background binding in the absence of crosslinker has been subtracted. Background values range from 500-1000 ng protein/μmol lipid. There was a tendency for background values to be somewhat (10-30%) higher in the presence of PEG-DSPE; this may not be significant. Multiple entries denote multiple separate crosslinking experiments.

2. Coupling by 3-(2-pyridyldithio) propionamide.

The reaction of dithio propionamides with the sulfhydryl group produces coupling to the sulfhydryl-containing molecules via a disulfide linkage.

Disulfide exchange occurs readily at pH 8, in a nonreducing environment. The method involves reaction of a thiol group in a peptide with a liposome prepared to contain PE-PEG (2-pyridyldithio) propionamide). The reaction couples the protein to the liposomes through a disulfide linkage as illustrated in Fig. 10 (compound XXXIV).

3. Reductive amination. In this procedure, the terminal hydroxyl group of a PEG chain, covalently linked at one end to PE, is converted to the aldehyde by mild oxidation. The oxidation step may be carried out before or after incorporation into liposomes to produce the aldehyde form of the derivatized lipid (compound XIII in Fig. 3). Reaction of the aldehyde with the amine group of an effector molecule gives the Schiff base (compound XXXV) which is then reduced to the desired derivatized lipid with amine-group linked peptide (XXXVI).

As indicated above, the polymers can also be activated for effector coupling in preformed lipids, i.e., with the polymer-derivatized lipids already incorporated into liposomes. One advantage of this approach is that only polymer moieties on the outer surface of the liposomes are activated. In one general approach, involving PEG polymers, the terminal OH groups are first oxidized by treatment with sodium periodate for 2 hours at 20°C in the dark. After oxidation, the excess reagent is removed, and the liposomes are incubated with the effector molecule, e.g. F_{ab} fragments, in the presence of 2M sodium cyanoborohydride (10 µl/ml) at 20°C for 14 hours. After completing the incubation, the liposomes were chromatographed on a Sepharose to remove free (non-linked) effector molecules.

III. Bloodstream and Tissue Retention of Liposomes Containing End-functionalized PEG-DSPE

In vivo studies were undertaken to determine the bloodstream and tissue retention of liposomes containing end-functionalized PEG-DSPE. End-functionalized PEG-DSPE contains a chemically active group which can be used for attaching a variety of compounds to liposomes. From these studies it has been determined that end-functionalization does not affect the extended lifetime in the bloodstream of liposomes containing PEG-DSPE, monomethoxy PEG-DSPE, or other similarly modified vesicle-forming lipids.

In experiments performed in support of the present invention, liposomes containing PEG-DSPE end-functionalized by hydrazide were prepared. The hydrazide group at the end of a PEG chain can be used for the introduction of other functional groups, or can be used in numerous types of conjugation schemes (Inman). Particularly useful is hydrazide's reactivity toward various glycoproteins, such as immunoglobulins (Wilchek), for attaching these molecules to liposomes.

Gallium 67-labelled, hydrazide end-functionalized PEG liposomes were injected in rats by tail vein injection at about 10-20 micromolar phospholipid/kg body weight. Blood samples were obtained by retroorbital bleeding at defined times. The percent of gallium labelled liposomes remaining in the bloodstream was determined at 0, 15 minutes, 1, 3, 5, and 24 hours and is presented in Table 3. The percent injected gallium 67-labelled liposome dose remaining in the blood stream at different times is illustrated in a half log plot versus time in Fig. 12.

After 24 hours the animals were sacrificed and tissues removed for label quantitation. The percent of the injected dose found in selected tissues at 24 hours is presented in Table 3.

The blood and tissue retention of Ga-labelled, hydrazide end-functionalized liposomes having two

different lipid compositions were also compared in Table 3. A fluid liposome composition was prepared from partially hydrogenated egg phosphatidylcholine (HPEPC). A typical liposome composition contains the hydrazide PEG-DSPE lipid, partially hydrogenated egg PC (PHEPC), and cholesterol in a lipid:lipid:lipid mole ratio of about 0.15:1.85:1. A rigid liposome composition was prepared by substituting hydrogenated serum phosphatidylcholine (HSPC) for PHEPC at the same mole ratio.

As is indicated in Table 3, the fluidity of the liposome composition does not affect the blood retention time of the liposomes. However, the fluidity of the liposome composition does appear to affect the tissue distribution of the end-functionalized liposome. For example, rigid liposomes are preferentially retained by liver, spleen and bone tissue. Fluid liposomes are preferentially retained by the kidneys, heart, skin and muscle tissue.

Table 3

Injected 67 GA Dose Detected at Specified Timepoints		
Blood	Peg-HZ Rigid	PEG-Hz Fluid
0	101.1 \pm 12.0	100.2 \pm 5.4
15 min.	89.6 \pm 11.2	81.6 \pm 2.5
1 hr.	84 \pm 11.1	81.7 \pm 7.4
3 hr.	76 \pm 10.5	75.3 \pm 5.1
5 hr.	71.7 \pm 10.7	66.3 \pm 3.8
24 hr.	33.4 \pm 6.8	34.3 \pm 0.68
Tissues at 24 hr.	Peg-HZ Rigid	Peg-Hz Fluid
liver	12.1 \pm 1.2	8.8 \pm 0.81
spleen	5.1 \pm 0.47	4.7 \pm 0.64
kidneys	1.4 \pm 0.22	1.7 \pm 0.25

* Injected 67 CA Dose Detected at Specified Timepoints		
heart	0.36 ± 0.037	0.77 ± 0.21
lungs	.62 ± 0.23	0.58 ± 0.03
skin	.086 ± 0.03	0.16 ± 0.08
muscle	.08 ± 0.03	0.29 ± 0.02
bone	.28 ± 0.09	0.04 ± 0.01

5

IV. Therapeutic Effector Compositions

Below are described specific embodiments of the effector composition of the invention, and their intended use as injectable therapeutic agents.

10

A. Compositions for Enhancing an Immune Response

In one general embodiment, the effector in the liposome composition is a molecule capable of enhancing an immune response when administered parenterally.

15

1. F₂ Effector. The F₂ effector composition is used as a passive vaccine to provide humoral immunity against one of a variety of selected pathogenic antigens. The composition is administered to supplement a weakened immune response to a given antigen.

20

The vaccine effector composition is administered intravenously shortly after exposure to, or shortly before expected exposure to a selected pathogen. The composition is preferably injected in an amount corresponding to between about 0.1 to 2 mg antibody/kg body weight. After IV administration, the composition circulates in the bloodstream, at an effective concentration, for 1-2 days.

25

2. CD4 Glycoprotein Effector. Numerous therapies for the prevention and treatment of human immunodeficiency virus (HIV) infection and acquired immune deficiency syndrome (AIDS) have been proposed. These therapies target different steps in the process of viral infection. Frequently, therapy includes the

30

administration of drugs which interfere with viral replication, such as AZT and DDI. The administration of these drugs is accompanied by toxic side effects, since the replication process of normal cells is also affected.

Another step in the process of viral infection which is targeted in therapy is viral attachment to cells. HIV binds with specificity to the CD4 receptor of CD4+ T cells. By mechanisms not yet fully understood, the CD4+ cells eventually can become infected by HIV. Soluble CD4 receptor polypeptides have been administered intravenously to HIV-infected patients to prevent further HIV infection of a patient's CD4+ T cell population. Heretofore, this therapy has not been effective, since CD4 receptor fragments are rapidly cleared from circulation in the blood stream, and inhibitory plasma concentrations cannot be maintained (Capon).

The effector molecule in this embodiment is a soluble CD4 receptor polypeptide capable of binding to the gp120 glycoprotein of human immunodeficiency virus (HIV) to prevent binding of HIV to CD4+ T cells. In a preferred embodiment covalent attachment of CD4 is accomplished by coupling periodate oxidized CD4 with hydrazide group containing liposomes.

CD4 administered as a long-circulating liposomal composition will remain in the blood stream for a longer period of time. The CD4 effector composition can be administered intravenously during early or late stages of HIV infection, most beneficially in combination with other drugs used in AIDS therapeutics, so that HIV particles bound to the liposomes, to the extent these are taken up by infectable cells, will also deliver a dose of the anti-viral agent to the infected cells. AZT and DDI are examples of anti-HIV drugs which may be encapsulated in the liposome compositions.

The liposome composition should be administered intravenously in a dose equivalent to an effective blood stream CD4 concentration of 1-10 micromolar. Doses of 5-40 mg CD4/kg body weight can be administered, typically at intervals of 2-14 days between treatments, with the level of HIV present in the bloodstream being monitored during treatment by standard assay methods.

Principal advantages of this composition are the increased circulation time of the CD4 effector in the blood stream and the polyvalent presentation of the effector on the surface of the liposomes. Improved affinities of polyvalent CD4 presentation has recently been described (Chen). As described above, CD4 receptor fragments are cleared rapidly by renal filtration. Covalent attachment of the CD4 polypeptide to liposomal carriers prevents renal clearance, and permits circulation of the polypeptide effector composition for 24-48 hours in the blood stream.

Additionally, the polyvalent CD4-bearing liposomes resemble CD4+ T cell lymphocytes in that the CD4 glycoproteins are presented on hydrophobic surfaces which mimic the surfaces of T cell lymphocytes. This presentation is likely to serve as a decoy binding HIV particles and HIV infected cells expressing gp120 so that healthy CD4+ lymphocytes are spared.

3. Effector for stimulating inflammatory immune responses. Some medical conditions are treated indirectly, by stimulation of the body's natural immune response. Such conditions can include immunodeficiency diseases, such as AIDS, chronic infectious, and certain types of cancers. One immunostimulant therapy involves intravenous injection of cytokines, which can acts to stimulate B cell and T cell immune responses in a variety of ways.

The cytokine effector composition may be administered on a short term basis to enhance a weak immunogenic or weak microbicidal response. Alternatively, the cytokine effector composition may also be administered on a long term basis as part of a therapy treatment for cancer or AIDS. The effector composition may be administered intravenously at doses of about 0.5 to 5.0 mg/kg body weight to enhance an immunogenic response. These doses result in an effective cytokine concentration of about 0.1-1 micromolar in the blood stream.

B. Compositions for Blocking Binding to Cell Receptors

In another general embodiment, the effector in the liposome composition is a molecule capable of blocking the binding of an endogenous agent to a cell receptor, to achieve a desired therapeutic effect.

1. ELAM-1 Binding Inhibitor. As one example, inflammation causes the expression of a polypeptide, endothelial leukocyte adhesion molecule-1 (ELAM-1), on the surface of endothelial cells of the blood vessels. ELAM-1, in turn, recognizes and binds a polysaccharide moiety on surfaces of neutrophils, and recruits neutrophils to sites of inflammation. By preventing the recognition and binding of neutrophils by ELAM-1, excessive inflammatory responses due to conditions, such as reperfusion injury, septic shock, and chronic inflammatory diseases, can be avoided.

In this embodiment, the effector is used to prevent the excessive recruitment of neutrophils to sites of inflammation in the blood stream. The effector is sialyl Lewis^x recognized by ELAM-1 (Phillips). This polysaccharide effector is covalently attached to long-circulating liposomal compositions by the methods described above. In a preferred embodiment attachment of sialyl Lewis^x to liposomes is accomplished via the reducing end of the glucosamine

residue. The reducing end can easily react with a hydrazide group of a DSPE-PEG preparation. Coupling of the polysaccharide to the liposomal carrier composition prevents the polysaccharide's clearance by the kidney, and maintains an effective concentration of the polysaccharide effector over a 48 hour period. The liposomal carrier composition is administered in doses of 10 to 50 micrograms/ kg body weight in a timely fashion, intravenously, and close to the site of inflammation.

2. - Inhibitor of IL-1 Activity. As a second example, the effector is IL-1 inhibitor, which inhibits IL-1's immunostimulatory activity, or IL-1 receptor antagonist (IL1RA), which blocks the binding of IL-1 to lymphocyte cell surfaces. These molecules may be administered to a subject for treatment of septic shock, toxic shock, colonic inflammation, or leukemic cell proliferation. In this aspect of the invention, the liposomal carrier composition is administered in doses of 20 to 50 micrograms/ kg body weight on a short term basis for the treatment sepsis, toxic shock or colonic inflammation. The liposomal carrier composition may also be administered at 1 to 2 day intervals on a long term basis for the treatment of leukemia.

Other molecules effective to block the binding of specific cytokines to specific lymphocyte populations may also be employed.

The use of the long-circulating effector composition, for use in blocking the binding of endogenous agents to cell receptor sites, provides two advantages over the use of free effector. First, the effector is maintained in the bloodstream over an extended period, by virtue of blocking renal clearance of the effector. Secondly, the effector molecule, in liposome-bound form, provides greater steric hindrance at the cell surface site of the receptor. Also, the

competitive binding or blocking effector and endogenous agent on the receptor site is shifted toward the blocking agent, since the liposomal structure will be displaced at a slower rate kinetically, due to its larger size and number of blocking molecules in the region of the receptor site.

3. Peptide Hormones. In this embodiment the effector composition is useful in the treatment of various diseases that respond to peptide hormones. In one embodiment, the effector is parathyroid hormone (PTH) which is effective to inhibit uncontrolled osteoblast division.

4. Peptide. In this embodiment, the effector is a short peptide that has cell-binding activity and is effective to compete with a ligand for a receptor site. Inhibition of the ligand-receptor cell-binding event potentially results in arresting the infection process.

In general, useful peptides will have cell-binding activity due to a portion of sequence other than the end of the peptide. In this way, after attachment to the polymer chain on the liposome, the peptide remains active. Another general feature of useful peptides is their small size. Peptides of between about 4-20 amino acids are preferred.

One exemplary peptide, YIGSR, identified herein as SEQ ID NO:6 (Figure 13), is useful for blocking metastases of tumors. SEQ ID NO:6 is one of the peptide sequences in the B1 chain of laminin responsible for the glycoprotein's adhesive properties and is known to bind to the laminin receptor. Laminin, the protein in which the YIGSR sequence occurs, is a constituent of basement membranes. Circulating metastatic cells which over-express the laminin receptor may find their way to laminin molecules in the basement membrane where they may become attached and establish metastatic tumors. By introducing exogenous YIGSR, the laminin receptors of

circulating metastatic cells are blocked, thereby inhibiting tumor establishment.

Similarly, the peptide arginine-glycine-aspartic acid-serine (RGDS) has experimentally been shown to inhibit the establishment of metastatic tumors by interfering with the binding of tumor cells to fibronectin (Humphries). Like YIGSR, RGDS is a peptide sequence involved with tumor cell adhesion to basement membranes.

The infection of lymphocytes by HIV also involves a specific peptide-receptor interaction (Nehete). Here, the receptor is the CD4 protein and the peptide is the HIV envelope protein gp120. The peptide binding sequences are located in the V3 loop of gp120. Several peptide sequences of between 8-15 amino acids have been implicated in the binding interactions. These sequences include SEQ ID NO:1 through SEQ ID NO:5 and are shown in Figure 13.

Pseudomonas cepacia infections also exhibit specific binding to the cells they infect (Sajjan). *Pseudomonas* pilin proteins, which are found on the bacterial cell surface, act as receptors for host proteins called mucins. Suitable peptides have been disclosed (e.g., Sastry, Lee).

25

C. Antimicrobial Composition

In this embodiment the effector is a compound which is useful in the prevention and treatment of septic shock. The causal agents of septic shock are endotoxins which accumulate during systemic gram-negative bacterial infections (Jawetz). Because of the rapid onset of severe sepsis, treatment is often not begun until critical stages of sepsis.

The antimicrobial agent which has been used most successfully in treating septic shock against in cases of septic shock is polymyxin B. Because the compound is rapidly excreted, high doses of polymyxin B are

required for effective treatment. The high doses, unfortunately, can lead to severe renal toxicity.

In the present invention, polymyxin B circulation in the bloodstream is extended several fold by its attachment to long-circulating liposomes. The compound is attached to long-circulating liposomal composition carriers by the coupling methods described above.

The liposomal composition is administered on a short term basis, at a dose of 0.1-0.5 mg/ kg body weight, as a prophylactic for individuals at risk of, or suffering from acute septic shock. Features of the polymyxin B liposomal composition, already discussed, will minimize polymyxin B's renal accumulation and renal toxicity.

The following examples illustrate methods for preparing derivatized lipids and protein-coated liposomes in accordance with the invention.

20

Example 1

Preparation of DSPE-PEG-Maleimide

I. Preparation of the Mono 2-nitrobenzenesulfonamide of PEG bis(amine) (compound II)

A mixture of 1.7 g (0.5 mmole) of commercially available polyethylene glycol bis(amine) and 104 mg (0.55 mmole) of 2-nitrobenzene sulfonyl chloride were added to a round-bottomed flask. The minimum amount of dioxane to effect solution (about 15 ml) and 280 microliters of triethylamine (2 mmole) were added. The reaction flask was stoppered and let to stand at room temperature for 4 days.

Thin layer chromatography (TLC) on silica coated plates using a solvent mixture of the following composition $\text{CHCl}_3/\text{CH}_3\text{OH}/\text{H}_2\text{O}/\text{NH}_4\text{OH}$; 130/ 70/ 8/ 0.5; v/v/v/v showed fluorescence quenching spots at $R_f = 0.87$ to 0.95 and $R_f = 0.68-0.75$. The 2-nitro benzene sulfonyl chloride was a more compact spot at $R_f = 0.85$. The UV absorbing material at $R_f = 0.87-0.95$ probably

represented the bis-2-nitro-benzenesulfenamide. The material at $R_f=0.68-0.75$ probably represented the desired mono-2-nitrobenzenesulfonamide of the starting diamine.

5 The solvent was evaporated under vacuum to obtain 2.135 g of a yellow syrup. It was dissolved in 5 ml chloroform and placed at the top of a 21 mm x 270 mm column of SiO₂ wetted with chloroform. The product was purified by passing through the column, in sequence:

10

100 ml	100% chloroform	0% (1% conc. NH ₄ OH in MeOH)
200 ml	90% "	10% "
100 ml	80% "	20% "
100 ml	70% "	30% "

15

Fifty ml aliquots were collected separately and assayed by TLC as described above. Most of the yellow, ninhydrin positive-reacting material was eluted in the 20% (1% conc. NH₄OH in MeOH) fraction. The fractions were dried and resulted in 397 mg of a bright yellow solid. The yield of the pure sample was about 20%.

20

II. Preparation of the Imidazole Carbamate of the Mono 2-nitrobenzenesulfonamide of PEG bis(amine) (compound III)

25

550 mg (0.15 mmole) of the 2-nitrobenzenesulfonamide of PEG bis(amine) were dissolved in anhydrous benzene. To this was added 49 mg of carbonyl diimidazole (0.3 mmole) and 28 microliters (0.20 mmole) of triethylamine. The air in the reaction vessel was displaced with nitrogen, the flask stoppered and heated in an 80 degree oil bath for 4 hours. TLC on silica-coated plates using the same solvent system as described above, showed that all the starting sulfonamide ($R_f=0.72$) had been consumed, and had been replaced by an iodine absorbing material at $R_f=0.92$. The solvent was removed under vacuum. The residue was dissolved in about 2.5 ml chloroform and transferred to the top of a 21 x 280 mm column of

35

silica which was wetted with chloroform. The following solvents were passed through the column, in sequence:

	100 ml	100% chloroform	0% (1% conc. NH_4OH in MeOH)
5	100 ml	90% "	10% "
	200 ml	80% "	20% "

50 ml fractions were collected and assayed by TLC, the desired product was found predominantly in the 20% (1% conc. NH_4OH in MeOH fraction). When the pooled fractions were evaporated to dryness, 475 mg of a lemon-yellow solid were obtained. This was dissolved in 4.75 ml benzene.

15 III. Preparation of the DSPE carbamide of the 2-nitrobenzene sulfonamide of PEG bis(amine)

To the 450 mg (0.125 mmole) of 2-nitrobenzenesulfonamide of the imidazole carbamide of the PEG bis(amine) dissolved in 4.5 ml benzene was added 93 mg DSPE (0.125 mmole) and 70 microliters (0.50 mmole) of triethylamine. The air was displaced with nitrogen, the flask stoppered and heated in an oil bath at 80 degrees for 6 hours. The flask was cooled to room temperature. DSPE migrates in the above described TLC system with an R_f of 0.54. TLC indicated that all the DSPE had been consumed. The solvent was evaporated under vacuum. The residue was dissolved in 2.5 ml chloroform and placed at the top of a 21 x 260 mm column of silica wetted with chloroform. The sample was purified by passing through the column in sequence:

	100 ml	100% chloroform	0% (1% conc. NH_4OH in MeOH)
	200 ml	90% "	10% "
	100 ml	80% "	20% "
35	100 ml	70% "	30% "

The desired product eluted at 20% (1% conc. NH_4OH in MeOH), was evaporated and afforded 358 mg of a bright yellow solid with an R_f = 0.95. Fractions

containing imidazole were not used and the final yield of the product (0.0837 mmoles) was 65%.

IV. Preparation of the DSPE Carbamide of PEG bis(amine) (compound IV)

5 About 358 mg of nitrobenzenesulfenamide of the DSPE carbamate of polyethyleneglycol bis (amine) were dissolved in 10 ml ethanol. To the solution were added 2.4 ml water and 1.2 ml acetic acid. The mixture was
10 allowed to stand at room temperature for 18 hours. TLC analysis showed only partial deprotection. Another 2.3 ml water, and another 1.2 ml acetic acid were added and the reaction was left standing overnight. On silicate
15 coated plates, using a similar solvent system as described above as the developer, fluorescence quenching material appeared at $R_f=0.86$ and $R_f=0.74$. The desired ninhydrin reactive, phosphate containing material migrated with an R_f value of 0.637. This spot showed
20 no fluorescence quenching.

The solvent was removed under vacuum. The residue
25 was redissolved in 15 ml chloroform and extracted with 15 ml 5% sodium carbonate. The mixture was centrifuged to effect separation, and the sodium carbonate phase was reextracted 2x with 15 ml chloroform. The combined
chloroform extracts were evaporated under reduced pressure to obtain 386 mg of wax. TLC indicated that the wax was largely a ninhydrin positive, phosphate containing lipid of $R_f=0.72$.

30 The wax was dissolved in 2.5 ml chloroform and placed on a silicate column which had been wetted with chloroform. The following solvents were passed through the column in sequence:

	100 ml of 100% chloroform	0% (1% CONC. NH_4OH in MeOH)
35	100 ml 90%	10%
	100 ml 80%	20%
	100 ml 70%	30%
	100 ml 50%	50%
	100 ml 0%	100%

The samples were assayed by TLC. The desired product was found in the fractions with 30% and 50% (1% conc. NH_4OH in methanol). These samples were combined and evaporated to dryness under vacuum to afford 91 mg (22 micromoles) of a viscous syrup.

V. Preparation of the Maleic Acid Derivative of the DSPE Carbamide of PEG bis(amine) (compound V)

To 18 micromoles of the DSPE carbamide of PEG bis(amine) described above, dissolved in 1.8 ml chloroform, was added 3.5 mg (36 micromoles) maleic anhydride and 5 microliters (36 micromoles) triethylamine. The stoppered flask was allowed to stand at room temperature for 24 hours. The solvent was evaporated. TLC on silica plates indicated that all the starting material, had been replaced by a ninhydrin negative, phosphate containing material of $R_f = 0.79-1.00$.

VI. Preparation of the Maleimide of the DSPE carbamide of PEG bis(amine) (compound VI)

The syrup was dissolved in 2 mls acetic anhydride saturated with anhydrous sodium acetate. The solution was heated in a 50 degree Centigrade oil bath for two hours. 10 ml ethanol were added and evaporated under vacuum. This step was repeated twice to remove excess acetic anhydride and acetic acid. The residue was taken up 1 ml chloroform, and passed through a silica column with the following solvents in sequence:

100 ml	100% chloroform	0% (1% conc. NH_4OH in MeOH)
200 ml	90% "	10% "
100 ml	80% "	20% "
100 ml	70% "	30% "

50 ml samples were collected, and the main product was found in the fractions eluted with 10% of 1% conc. NH_4OH in MeOH. The fractions were combined and then evaporated to dryness under vacuum which afforded 52 mg

of a pale, yellow, viscous oil, which by TLC migrated with an R_f of 0.98 and contained phosphate. 12.3 micromoles product were obtained which correspond to a yield of about 34%.

5

Example 2

Preparation DSPE-PEG 3-(2-pyridyldithio) propionamide

The DSPE carbamide of PEG bis (amine) (50 micromoles) is dissolved in 3 ml of anhydrous methanol containing 50 micromoles of triethylamine and 25 mg of N-succinimidyl 3-(2-pyridyldithio) propionate (SPDP). The reaction is carried out at room temperature for 5 hours under an argon atmosphere. Methanol is removed under reduced pressure, and the products were redissolved in chloroform and applied to a 10 ml silica gel column which had been activated at 150 degrees overnight and had been prewashed. A similar solvent system as used in Example 1 is used to purify the product. Analysis on TLC plates indicates a product with an R_f 0.98 which reacts negatively with ninhydrin, contains phosphate and has no free sulfhydryl groups. When the product is treated with excess dithiothreitol, 2-thiopyridinone is released.

25

Example 3

Preparation of the Aldehyde of the Ethylene-Linked PEG-DSPE

I. Preparation of I-trimethylsilyloxy-PEG (compound X)

15.0 gm (10 mmoles) of PEG) M.Wt. 1500, (Aldrich Chemical) was dissolved in 80 ml benzene. 1.40 ml (11 mmoles) of chlorotrimethyl silane (Aldrich Chemical Co.) and 1.53 ml (1mmoles) of triethylamine was added. The mixture was stirred at room temperature under an inert atmosphere for 5 hours.

35

The mixture was filtered by suction to separate crystals of triethylammonium chloride and the crystals were washed with 5 ml benzene. Filtrate and benzene

wash liquids were combined. This solution was evaporated to dryness under vacuum to provide 15.83 grams of colorless oil which solidified on standing.

TLC of the product on Si-C₁₈ reversed-phase plates using a mixture of 4 volumes of ethanol with 1 volume of water as developer, and iodine vapor visualization, revealed that all the polyglycol 1500 ($R_f=0.93$) has been consumed, and was replaced by a material of $R_f=0.82$. An infra-red spectrum revealed absorption peaks characteristic only of polyglycols.

Yield of I-trimethylsilyloxyPEG, M.W. 1500 was nearly quantitative.

II. Preparation of Trifluoromethane Sulfonyl Ester of Trimethylsilyloxy-PEG (compound XI)

15.74 grams (10 mmol) of the crystalline I-trimethylsilyloxy PEG obtained above was dissolved in 40 ml anhydrous benzene and cooled in a bath of crushed ice. 1.53 ml (11 mmol) triethylamine and 1.85 ml (11 mmol) of trifluoromethanesulfonic anhydride obtained from Aldrich Chemical Co. were added and the mixture was stirred over night under an inert atmosphere until the reaction mixture changed to a brown color.

The solvent was then evaporated under reduced pressure and the residual syrupy paste was diluted to 100.0 ml with methylene chloride. Because of the great reactivity of trifluoromethane sulfonic esters, no further purification of the trifluoromethane sulfonyl ester of I-trimethylsilyloxy PEG was done.

III. Preparation of N-1-trimethylsilyloxy PEG 1500 PE (compound XII)

10 ml of the methylene chloride stock solution of the trifluoromethane sulfonyl ester of 1-trimethylsilyloxy PEG was evaporated to dryness under vacuum to obtain about 1.2 grams of residue (approximately 0.7 mmoles). To this residue, 3.72 ml of a chloroform solution containing 372 mg (0.5 mmoles) egg

PE was added. To the resulting solution, 139
microliters (1.0 mmole) of triethylamine was added and
the solvent was evaporated under vacuum. To th
obtained residue, 5 ml dry dimethyl formamide and 70
5 microliters (0.50 mmoles) triethylamine (VI) was added.
Air from the reaction vessel was displaced with
nitrogen. The vessel was closed and heated in a sand
bath a 110°C for 22 hours. The solvent was evaporated
under vacuum to obtain 1.58 grams of brownish colored
10 oil.

A 21 x 260 mm chromatographic absorption column
filled with Kieselgel 60 silica 70-230 mesh, was
prepared and rinsed with a solvent composed of 40
volumes of butanone, 25 volumes acetic acid and 5
15 volumes of water. The crude product was dissolved in 3
ml of the same solvent and transferred to the top of
the chromatography column. The chromatogram was
developed with the same solvent and sequential 30 ml
portions of effluent were assayed each by TLC.

20 The TLC assay system used silica gel coated glass
plates, with solvent combination butanone/acetic
acid/water; 40/25/5; v/v/v. Iodine vapor absorption
served for visualization. In this solvent system, the
N-1-trimethylsilyloxy PEG 1500 PE appeared at $R_f=0.78$.
25 Unchanged PE appeared at $R_f=0.68$.

The desired N-1-trimethylsilyloxy PEG 1500 PE was
a chief constituent of the 170-300 ml portions of
column effluent. When evaporated to dryness under
vacuum these portions afforded 111 mg of pale yellow
30 oil of product.

IV. Preparation of N-polyethylene glycol 1500: PE (compound XII)

Once-chromatographed, PE compound was dissolved in
35 2 ml of tetrahydrofuran. To this, 6 ml acetic acid and
2 ml water was added. The resulting solution was let
to stand for 3 days at 23°C. The solvent from the
reaction mixture was evaporated under vacuum and dried

to constant weight to obtain 75 mg of pale yellow wax. TLC on Si-C18 reversed-phase plates, developed with a mixture of 4 volumes ethanol, 1 volume water, indicated that some free PE and some polyglycol-like material
5 formed during the hydrolysis.

The residue was dissolved in 0.5 ml tetrahydrofuran and diluted with 3 ml of a solution of ethanol water; 80:20; v:v. The mixture was applied to the top of a 10 mm x 250 mm chromatographic absorption
10 column packed with octadecyl bonded phase silica gel and column was developed with ethanol water 80:20% by volume, collecting sequential 20 ml portions of effluent. The effluent was assayed by reversed phase TLC. Fractions containing only product of $R_f=0.08$ to
15 0.15 were combined. This was typically the 20-100 ml portion of effluent. When evaporated to dryness, under vacuum, these portions afforded 33 mg of colorless wax PEG-PE corresponding to a yield of only 3%, based on the starting phosphatidyl ethanolamine.

20 NMR analysis indicated that the product incorporated both PE residues and PEG residues. The product prepared was used for a preparation of PEG-PE liposomes.

25 V. Preparation of the Aldehyde of PEG-DSPE (compound XIII)

The free hydroxyl group on PEG derivatized by DSPE can be oxidized to the corresponding aldehyde in the following manner prior to incorporation of the linear
30 polymers into liposomes (Harris). About 2.7 g PEG1500-DSPE (1 mmole), which is prepared as in Example 3, is added to 0.4 g acetic anhydride in 15 ml dimethylsulfoxide with stirring for 30 hours at room temperature. At this point the reaction mixture is
35 neutralized with dilute sodium hydroxide, the solvent is evaporated under reduced pressure.

The residue is dissolved in 10 ml chloroform, washed with two successive 10 ml portions of water, and

centrifuged to separate chloroform and water phases. The chloroform phase is evaporated under vacuum to obtain a wax. The wax is re-dissolved in 5 ml chloroform and transferred to the top of a 21 x 270 mm column of silica gel moistened with chloroform. The column is developed by passing 100 ml of solvent through the column. The following solvents were used in sequence:

	Volume % <u>Chloroform</u>	Volume % Methanol Containing <u>2% Conc. Ammonium Hydroxide/methanol</u>
10	100%	0%
	95%	5%
15	90%	10%
	85%	15%
	80%	20%
	70%	30%
	60%	40%
20	50%	50%
	0%	100%

Separated 50 ml fractions of column effluent are saved. The fractions of the column are separated by TLC on Si-C18 reversed-phase plates. TLC plates are developed with 4 volumes of ethanol mixed with 1 volume of water. Visualization is done by exposure to iodine vapor.

Only those fractions containing an iodine-absorbing lipid of R_f about 0.20 were combined and evaporated to dryness under vacuum and dried in high vacuum to constant weight. In this way 94 mg of waxy crystalline solid was obtained of M.W. 2226. The conversion of the terminal alcohol to the aldehyde can be monitored by IR.

Example 4

Synthesis of N-hydroxysuccinimide ester of α -hydroxy- ω -(carboxymethylamino-carbonyl)oxy-poly(oxyethylene) (Compound XXIV)
and Coupling to DSPE

α -hydroxy- ω -carboxy derivative of PEG (XXIX) (2 g, ≈ 1 mmol) and N-hydroxysuccinimide (0.23 g, 2 mmol)

were dissolved in methylene chloride-ethyl acetate (4 ml, 1:1). The solution was cooled on ice-water bath and treated with dicyclohexylcarbodiimide (DCC) (0.25 g, 1.2 mmol) predissolved in ethyl acetate (1 ml).
5 Within a few minutes the solution became cloudy as dicyclohexylurea (DCU) appeared. After 2 hours the reaction mixture was filtered from DCU and evaporated into dryness. The polymer was crystallized from isopropanol and dried in vacuo over P_2O_5 . Yield: 1.5 g
10 (70%). Titration of the product for active acyl content (Zalipsky, 1991) gave $4.8 \cdot 10^{-5}$ mole/g (104% of the theoretical value). H-NMR ($CDCl_3$) spectra showed in addition to characteristic singlets of PEG ($\delta = 3.64$) and N-hydroxysuccinimide ($\delta = 2.84$) also triplet
15 of $CH_2-(C=O)-Gly$ ($\delta = 4.27$) and doublet of methylene group of Glycine residue ($\delta = 4.33$) some isopropanol was also present ($\delta = 1.20, 3, J = 6$ Hz).

N-hydroxysuccinimide ester of α -hydroxy- ω -carboxy-PEG (0.52 g, 0.2 mmol) was added to DSPE (0.14 g, 0.185
20 mmol) suspension in chloroform (2 ml) followed by triethylamine (0.1 ml, 0.86 mmol). After mixing the mixture was heated on water bath at 55°C for 5 minutes. During this time the solution became clear. TLC (chloroform-methanol-water 90:18:2) on silica gel G
25 showed complete conversion of DSPE into a new product, which gave no color with ninhydrin yet like excess of PEG was readily visualized by iodine vapor. The solution was treated with an equivalent amount of acetic acid to neutralize the TEA and evaporated into
30 dryness. The residue was dissolved in water and extensively dialyzed through 300,000 MWCO cellulose acetate membrane at 4°C, filtered through 0.2 μm and lyophilized, yielding pure compound XXIV (360 mg, \approx 70%).

Example 5Preparation of DSPE-PEG-Hydrazide (Compound XXXII)

I. Preparation of ω -Hydroxy Acid Derivative of PEG, α -(Hydroxyethyl)- ω -(carboxymethyl-aminocarbonyl)oxy-poly(oxyethylene) (Compounds XIX and XXIX)

5 Polyethylene glycol (Fluka, PEG-2000, 42 g, 42 mequiv OH) is dissolved in toluene (200 ml) and azeotropically dried (Zalipsky, 1987), and treated with
10 ethyl isocyanatoacetate (2.3 ml, 21 mmol) and triethylamine (1.5 ml, 10 mmol). After overnight reaction at 25°C the solution is evaporated to dryness. The residue is dissolved in 0.2 M NaOH (100 ml) and any trace of toluene is evaporated. The solution is
15 maintained at pH 12 with periodical dropwise additions of 4 M NaOH.

When the solution pH is stabilized at pH 12, the solution is acidified to pH 3.0 and the product is extracted with methylene chloride (100 ml \times 2). TLC on
20 silica gel G (isopropyl alcohol/H₂O/conc. ammonia 10:2:1) gives a typical chromatogram of partially carboxylated PEG (Zalipsky, 1990) consisting of unreacted PEG (R_f = 0.67), monocarboxylated derivative (R_f = 0.55) and dicarboxylated derivative of the
25 polymer (R_f = 0.47). This solution is dried over (MgSO₄), filtered and evaporated to dryness. The PEG mixture is dissolved in water (50 ml). One-third of this solution (30 ml \approx 14 g of derivatized PEG) is loaded onto DEAE-Sephadex A-25 (115 ml of gel in borate
30 form). After the underivatized PEG is washed off the column with water (confirmed by negative polymethacrylic acid (PMA) test, (Zalipsky, 1990) gradient of ammonium bicarbonate (2-20 mM at increments of 1-2 mM every 200 ml) was applied, and 50 ml fractions collected.
35 Fractions 1-25 contain only PEG monoacid as determined by PMA and TLC tests. These fractions are pooled together, concentrated to \approx 70 ml, acidified to pH 2 and extracted with methylene chloride (50 ml \times 2). The

CH₂Cl₂ solution is dried (MgSO₄), concentrated and poured into cold stirring ether. The precipitated product is dried in vacuo. Yield: 7 g. Titration of carboxyl groups gives $4.6 \cdot 10^{-4}$ mequiv/g (97% of theoretical value).

II. Preparation of Compound XXX

The ω -hydroxy acid derivative of PEG (5 g, 2.38 mmol) and tert-butyl carbazate (0.91 g, 6.9 mmol) are dissolved in CH₂Cl₂-ethyl acetate (1:1, 7 ml). The solution is cooled on ice and treated with DCC (0.6 g, 2.9 mmol) predissolved in the same solvent mixture. After 30 minutes the ice bath is removed and the reaction is allowed to proceed for an additional 3 hours. The reaction mixture is filtered from dicyclohexylurea and evaporated. The product is recovered and purified by two precipitations from ethyl acetate-ether (1:1) and dried in vacuo over P₂O₅. Yield: 5.2 g, 98%. TLC of the product gave one spot (R_f = 0.68) instead of the starting material (R_f = 0.55). H-NMR (CDCl₃): δ 1.46 (s, t-Bu, 9H); 3.64 (s, PEG, 178H); 3.93 (br. d, J = 4.5, CH₂ of Gly, 2H); 4.24 (t, CH₂-OCO-Gly, 2H) ppm. ¹³C-NMR (CDCl₃): δ 28.1 (t-Bu); 43.4 (CH₂ of Gly); 61.6 (CH₂OH); 64.3 (CH₂OCOONH); 69.3 (CH₂CH₂OCOONH); 70.5 (PEG); 72.4 (CH₂CH₂OH); 81.0 (CMe₃); 155.1 (C=O of Boc); 156.4 (C=O of Gly urethane); 168.7 (C=O of Gly hydrazide) ppm.

III. Preparation of Compound XXXI

The ω -hydroxy Boc-hydrazide derivative of PEG (5 g, 2.26 mmol) is dissolved in pyridine (1.1 ml), CH₂Cl₂ (5 ml) and CH₃CN (2 ml) and treated with disuccinimidyl carbonate (1.4 g, 5.5 mmol) at 25°C overnight. The solution is filtered and gradually added to cold ethyl ether (100 ml). The precipitated product is dissolved in warm ethyl acetate (45 ml), chilled and mixed with equal volume of ethyl ether. The precipitate is

collected by filtration and dried in vacuo over P_2O_5 .
Yield: 4.8 g, 90%. Succinimidyl carbonate groups
content $4.15 \cdot 10^{-4}$ mequiv/g (98% of theoretical value)
was determined by titration (Zalipsky, 1991). H-NMR
(CDCl₃): δ 1.46 (s, t-Bu, 9H); 2.83 (s, succinimide);
3.64 (s, PEG, 178H); 3.79 (t, CH₂CH₂OCO₂-Su); 3.93 (br.
d, J = 4.5, CH₂ of Gly, 2H); 4.24 (t, CH₂-OCO-Gly, 2H);
4.46 (t, CH₂OCO₂-Su) ppm.

10 IV. Preparation of Compound XXXII

To prepare the DSPE-PEG-hydrazide a slight excess
of succinimidyl carbonate Boc-protected PEG-glycine
hydrazide, prepared above, is reacted with DSPE
suspended in chloroform in the presence of
15 triethylamine. The lipid derivative is quickly (5-10
minutes) solubilized in the process of this reaction.
The excess of heterobifunctional PEG is removed by
dialysis using 300,000 MWCO cellulose ester dialysis
membrane from Spectrum. The recovered lipid conjugate
20 was subjected to conventional Boc-deprotection
conditions (4M HCl in dioxane for 30 minutes) and then
further purified by recrystallization. H-NMR (CDCl₃):
 δ 0.88 (t, CH₃, 6H); 1.59 (t, CH₂CH₂CO, 4H); 2.84 (t,
CH₂CO, 4H); 3.64 (s, PEG, 180H); 4.0 (t); 4.2 (m,
25 CH₂OCO-NH₂); 4.4-4.3 (two doublets); 5.2 (g, CH of
glyceride).

Example 6

30 Preparation of Liposomes with Covalently Bound β -Galactosidase

The maleimide of the DSPE carbamate of
polyoxyethylene bis (amine) (3500-DSPE) was prepared as
in Example 1. β -Galactosidase was purchased from
Pierce (Rockford, IL). Enzyme assays with o-
35 nitrophenyl galactose were performed essentially by
monitoring the development of the colored product with
an extinction coefficient of 4467 at 413 nanometers in
0.1 N sodium hydroxide. The assay mixture consisted of

86 mM sodium phosphate pH 7.3, 1 mM magnesium chloride, 50 mM beta-mercaptoethanol and 2.3 mM o-nitrophenyl galactose and product formation was monitored for 10 to 15 minutes in the linear range of the assay.

- 5 Liposomes (MLV's) were prepared according to standard methods and sized with one of the following compositions indicated in Table 4. The liposomes were sized by extrusion through a polycarbonate membrane to 200 nm.

10

Table 4

"Phenotype"		Mol. %					
PEG-DSPE	Crosslinker	α T	Ch	PC	Crosslinker	PEG-DSPE	PG
-	-	1	33	61	-	-	5
+	-	1	33	61	-	5	-
-	+	1	33	56	5	-	5
+	+	1	33	56	5	5	-

15

- where α -T = α -tocopherol (antioxidant), Ch = cholesterol, PC = partially hydrogenated egg PC (IV 40), crosslinker=the maleimide derivative of PEG3500-DSPE, and PG = egg phosphatidyl glycerol. In addition all liposome preparations were "spiked" with a 3 H-DPPC tracer. The total lipid concentration in each preparation, after hydration in PBS (50 mM sodium phosphate pH 7.2, 50 mM sodium chloride, was 2 mM.

25

- Crosslinking reactions were performed by adding enzyme solution to the liposomes (final protein concentration = 0.5 mg/ml) and incubating the suspension overnight at ambient temperature with gentle shaking. Unreacted crosslinker was then quenched with 10 mM 2-mercaptoethanol (2-ME) for 30-60 minutes at 37°C. Liposomes were separated from unconjugated protein by flotation through a metrizamide gradient: the sample was brought to 30% (w/v) metrizamide and transferred to an SW60Ti tube, 20% metrizamide was layered above, then PBS was added on top to provide an aqueous interface.

35

Gradients were centrifuged at 45,000 rpm for 60 minutes at 4°C, then each liposomal band, easily visible at the PBS interface, was collected and transferred to dialysis tubing. Dialysis proceeded overnight at 4°C against two changes of PBS. Removal of the metrizamide was necessary because it inhibits β -galactosidase activity significantly even at 1% (w/v) concentration.

Example 6

10

Liposome Blood Lifetime Measurements of Hydrazide End-functionalized PEG Liposomes

I. Preparation of Hydrazide End-functionalized Liposomes

Hydrazide PEG-DSPE composed of PEG, end-functionalized with a hydrazide group, and distearyl-PE was prepared as described. The hydrazide PEG-DSPE lipid was combined with partially hydrogenated egg PC (PHEPC) and cholesterol in a lipid:lipid:lipid mole ratio of about 0.15:1.85:1 and the lipid mixture was hydrated.

Generally, lipid hydration occurred in the presence of desferal mesylate, followed by sizing to 0.1 micron, and removal of non-entrapped desferal by gel filtration with subsequent loading of Ga-oxide into the liposomes. The unencapsulated Ga was removed during passage through a Sephadex G-50 gel exclusion column. Both compositions contained 10 micromoles/ml in 0.15 M NaCl, 5 mM desferal.

A second lipid mixture was prepared in a similar manner but with HSPC instead of PHEPC.

30

II. Measuring Blood Circulation Time and Tissue Levels

In vivo studies of liposomes were performed in laboratory rats at 200-300 g each. These studies involved tail vein injection of liposome samples at about 10-20 micromolar phospholipid/kg body weight. Blood sample were obtained by retroorbital bleeding at defined times. The animals were sacrificed after 24 hours and tissues removed for label quantitation. The weight and

percent of the injected dose in each tissue was determined. The studies were carried out using ^{67}Ga -desferal loaded liposomes and radioactivity was measured using a gamma count r. The percent of the injected dose remaining in the blood at several time points up to 24 hours, and in selected tissues at 24 hours was determined.

A. Plasma Kinetics of Hydrazide-PEG Liposomes

The liposome composition (0.4 ml) was injected IV in animals. At times 0, 0.25, 1, 3, or 5 and 24 hours after injection, blood samples were removed and assayed for the amount of Ga-desferal remaining in the blood, expressed as a percentage of the amount measured immediately after injection. Hydrazide-PEG liposome have a blood half-life of about 15 hours, and nearly 30% of the injected material is present in the blood after 24 hours.

B. 24 Hour Tissue Levels

Studies to determine the distribution of gallium labelled liposomes in selected tissues, 24 hours after intravenous liposome injection, were carried out. The liposome composition (0.4 ml) was injected IV in animals. The percent dose remaining in tissues 24 hours after intravenous administration is shown in Table 3.

While the invention has been described with reference to specific methods and embodiments, it will be appreciated that various modifications and changes may be made without departing from the invention.

IT IS CLAIMED:

1. In a method of treating a subject by parenteral administration of a polypeptide or polysaccharide effector which is rapidly removed from the bloodstream by renal clearance in free form, the improvement comprising
parenterally administering to the subject, a liposome composition containing liposomes having an outer layer of polyethylene glycol chains and said effector covalently attached to the distal ends of said chains.
2. The method claim 1, wherein the polyethylene glycol chains have a molecular weight between about 1,000 and 10,000 daltons.
3. The method of claim 2, wherein the effector is selected from the group consisting of:
 - (a) an antibody F_{ab} fragment specific against a pathogen present in the bloodstream, for use in treating the subject for infection by the pathogen;
 - (b) a CD4 glycoprotein, for use in treating the subject for infection by human immunodeficiency virus (HIV);
 - (c) a cytokine or a cellular growth factor, for use in stimulating an immune response in the subject;
 - (d) a polysaccharide which binds to endothelial leukocyte adhesion molecule (ELAM), for use in treating inflammation related to neutrophil recruitment and tissue infiltration;
 - (e) IL-1 inhibitor or IL-1RA, for treating a subject to achieve immune-response suppression;
 - (f) polymyxin B or polymyxin B decapeptide, for treating the subject for septic shock;
 - (g) a peptide hormone, for treating a subject to regulate cellular growth; and

(h) a peptide, for inhibiting a ligand-receptor cell-binding event.

4. The method of claim 3, for use in treating the
5 subject for septic shock, wherein the effector is polymyxin B.

5. A liposome composition for use in preventing
rapid removal from the bloodstream of a polypeptide or
10 polysaccharide effector by renal clearance, comprising
liposomes, each having an outer layer of
polyethylene glycol chains, and

attached to the distal ends of said chains, an
effector selected from the group consisting of:

- 15 (a) an antibody F_{ab} fragment specific against a
pathogen in the bloodstream;
(b) a CD4 glycoprotein;
(c) a cytokine;
(d) a polysaccharide which binds to endothelial
20 leukocyte adhesion molecule (ELAM);
(e) IL-1 inhibitor or IL-1RA;
(f) polymyxin B;
(g) a peptide hormone; and
(h) a peptide.

25

6. The composition of claim 5, wherein the
polyethylene glycol chains have a molecular weight
between about 1,000 and 10,000 daltons.

30 7. The composition of claim 6, for use in
treating the subject for septic shock, wherein the
effector is polymyxin B.

INTERNATIONAL SEARCH REPORT

Int. Appl. No.

PCT/US 94/03103

A. CLASSIFICATION OF SUBJECT MATTER
IPC 5 A61K9/127

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)
IPC 5 A61K G01N

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practical, search terms used)

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category *	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
A	JOURNAL OF LIPOSOME RESEARCH vol. 2, no. 3, 1992, NEW YORK (US) pages 321 - 334 XP303896 A.L. KLIBANOV ET AL. 'long-circulating liposomes: development and perspectives' see the whole document see page 330; figure B see page 331 - paragraph 2 ---	1-7
A	EP, A, 0 526 700 (MITSUBISHI KASEI CORPORATION) 10 February 1993 see the whole document ---	1-7
-/--		

☒ Further documents are listed in the continuation of box C.☒ Patent family members are listed in annex.

* Special categories of cited documents:

- *A* document defining the general state of the art which is not considered to be of particular relevance
- *E* earlier document but published on or after the international filing date
- *L* document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
- *O* document referring to an oral disclosure, use, exhibition or other means
- *P* document published prior to the international filing date but later than the priority date claimed

T later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

X document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

Y document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.

INTERNATIONAL SEARCH REPORT

1. International application No.

PCT/US94/03103

Box I Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet)

This international search report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☒ Claims Nos.:
because they relate to subject matter not required to be searched by this Authority, namely:
Remark: Although claims 1-4 are directed to a method of treatment of the human/animal body the search has been carried out and based on the alleged effects of the composition.
2. ☐ Claims Nos.:
because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out, specifically:
3. ☐ Claims Nos.:
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

1. ☐ As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims.
2. ☐ As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.
3. ☐ As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims for which fees were paid, specifically claims Nos.:
4. ☐ No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

Remark on Protest

- ☐ The additional search fees were accompanied by the applicant's protest.
- ☐ No protest accompanied the payment of additional search fees.
